The main purpose of this study was to examine the relationships between the big five personality traits and happiness with religious orientation as a mediator. The participants consisted of 301 Shiraz University students (110 males and 191 females) selected by applying a multistage random sampling method. Participants completed three questionnaires: NEO-FFI or the short personality inventory of Costa and Mc Crae (1992); the Intrinsic-Extrinsic Religious Orientation Scale (IEROS, Allport & Ross, 1967); and the Oxford Happiness Inventory (OHI) (Argyle, 1989). These instruments showed appropriate reliability and validity. Multiple regression and path analysis were the major statistical analyses run in the study. Results of multiple regressions revealed that extraversion, and intrinsic religious orientations were the positive predictors of happiness, in contrast to Neuroticism which predicted happiness negatively. Also, results showed that religion orientation played the mediation role between these relationships. The findings indicated that this model is a proper model to explain the mechanism of the effects of personality traits on happiness. Based on the findings, to increase the level of happiness in neurotic people it would seem useful to intervene by increasing the intrinsic religious orientation.

Keywords: the big five personality traits, religious orientation, happiness, students

During the last century, researchers and psychologists have

mostly emphasized the disappointment and unhappiness conditions of human beings such as anxiety and depression rather than their positive strengths and potentialities. In recent years, especially since Martin Seligman was appointed as the APA president, a gradual trend has appeared in researchers' attitudes toward the positive aspects of human strengths (Furnham and Cheng, 2000, 2003; khanzadeh, Moltafet, and Sadati, 2007). Positive psychology does not focus so much on what is wrong, bad, or pathological about people and their ways of being, thinking and acting. Positive psychology guiding question is what strengths do people bring to deal effectively with their lives, rather than pathology focus (Snyder, 2002)? Within the last decade, for instance, some psychologists and researchers have tried to bring some new definitions for the happiness predictor variables. In conceptualization of happiness Argyle (1989, 2001) defined happiness as having three independent components: (1) the average level of satisfaction over a specific time period; (2) the frequency and degree of positive effects; (3) the relative absence of negative effects. The review of the literature shows that a vast majority of the studies have supported the relationship between personality traits (especially extraversion and neuroticism) and happiness. For instance, bodies of the studies indicate that individuals with high score on extraversion and/or low on neuroticism tend to show more happiness (Eysenck, 1990; Argyle, 1990; Emmons & Diener, 1985; Furnham and Cheng, 2000, 2003; Francies & Robin, 2000; Francies & katz, 2002; khanzadeh, Moltafet, and Sadati, 2007). Religion constructs has been found as the predictors of happiness. Some researchers such as Allport & Ross (1967), Batson (1993) and Maltby (1999) have demonstrated that individuals differ in their religious orientation and these differences are related to variations in personality,

happiness, religious experience (Altemeyer & Hunsberger, 1992). Allport (1967) has proposed two main religious orientations: intrinsic and extrinsic. Individuals with an intrinsic orientation toward religion were described as wholly committed toward their religious beliefs and that religiosity was evident in every aspect of their life. On the other hand, those with an extrinsic orientation used religion as a means to provide participation in a powerful in-group protection (Genia, 1993), consolation and social status (Allport & Ross, 1967), religious participation and an ego defense. This difference between religious orientations is said to be related to the personality traits, and this difference has an effect on happiness. For example, in a qualitative review of the relationship between religiosity and personality trait, Francis (1993, 1997) reported a negative relationship between religiosity and psychoticism. Saroglou (2002) in a meta-analysis study, using the five factors model of personality, found that general religiosity was related to extroversion, agreeableness and conscientiousness. He found that intrinsic religious orientation was related to low agreeableness, low neuroticism and low openness, while extrinsic religious orientation was related to neuroticism.

Researchers and practitioners in various fields of study (e.g., psychology, sociology and medicine) have shown interest in whether religion influences mental health (Batson, Schoenrade & Ventis, 1993; Laurencell & Abeell 2002; Mazidi & Ostovar, 2006). The literature review identified numerous studies investigating this link in various populations. While some studies confirm a positive relationship between religion and mental health, others report no or even negative relationships (Gartner, Larson, & Allen, 1991). Francis & Robbins (2000) have demonstrated a significant positive association between scores on the Oxford Happiness Inventory and scores on Francis

scale of Attitude toward Christianity. Some researchers revealed that intrinsic and extrinsic religious orientations predicted higher and lower levels of well-being and happiness, respectively (Francis & Wilcox, 2000; Dezutter, Socnes & Husebaut 2006; Maltby & Day 2000, 2003). In sum, studies are consistent in reporting a significant negative relationship between the intrinsic orientation toward religion and depressive symptoms and trait anxiety and a significant positive relationship between extrinsic orientation toward religion and depressive symptoms and trait anxiety (Dezutter, Socnes & Husebaut, 2006; Maltby & Day, 2000, 2003; Goodin, Kronfli, King, Glover, Sibille & Fillingim, 2012).

Although the previous studies have mainly confirmed the positive relationships of personality traits and religious orientation with happiness, they did not clearly mention the mechanism of these relationships. Therefore, the main goal of the present study is to explore the effects of personality dimensions on happiness with religious orientation as a mediation variable.

Based on our research purpose, three research hypotheses are generated:

1. There is a relationship between each of the personality dimensions and happiness.
2. There is a relationship between each of the Personality dimensions and religious orientation.
3. Religious orientation has a mediation role between personality dimensions and happiness.

Method

The population included all bachelor students who studied at Shiraz University in 2011-2012 years. The sample was selected

by the random multistage sampling method from the four faculties of Shiraz University (engineer faculty, education and psychology faculty, agriculture faculty and humanities faculty). The participants consisted of 301 bachelor Shiraz University students (110 males and 191 females) with age ranging between 18 and 24 years. All participants were informed in class that they would be asked to participate in a research study of personality, motivational beliefs and hope, and informed consent was obtained.

Measures

Three questionnaires were administered to collect the data:

Personality

Participants completed the authorized Dutch/Flemish version of the NEO-FFI which is a 60-item self-report scale with five subscales named as: Extraversion, Agreeableness, Conscientiousness, Neuroticism and Openness to Experience (Hoekstra, Ormel & Fruyt, 1996). Each subscale contains 12 five-point Likert-type items with a proper reliability Cronbach's alpha rating from .67 to .87 for all subscales (Duriez & Soenens 2006). In this study the values of Cronbach's alpha obtained were from .76 to .88. The results of the factor analysis showed five general factors which explained 38.51 percent of the variance. The factor loadings obtained were from .42 to .73 for the items.

Intrinsic-Extrinsic Religious Orientation Scale (IEROS). The IEROS is a scale for measuring religious orientation which was originally designed as to define the construct as consisted of two dimensions, intrinsic and extrinsic. The IEROS is a 20 four-point Likert-type scale. Based on its original construction, nine

items are related to Intrinsic (INT) and 11 items represent the extrinsic (EXT) scale. The psychometric qualities of IEROS produce evidence of satisfactory reliability. Values of Cronbach's alpha were .65 to .66 for the extrinsic scale scores and .79 to .82 for the intrinsic ones (Taylor & Mac Donald, 1999; Genia, 1993). Values of Cronbach's alpha for this study were .76 for extrinsic and .84 for intrinsic scales. Validity of the instrument has also been provided (Genia, 1993; Taylor & Mac Donald, 1999). Results of the factor analysis showed two general factors, explaining 29.6 percent of the variance. Factor loadings obtained were from .36 to .69.

Oxford Happiness Inventory (OHI). The OHI is a 29 self-rating Likert-type items, to measure the level of happiness. The OHI seems to demonstrate excellent reliability (test-retest= .78 and Cronbach's alpha from .64 to .87 (Cheng & Furnham, 2003.)). Correlations among all the happiness components (positive effects, life satisfaction, as well as negative effects, depression and distress) varied from .40 to .60 confirming acceptable validity for the measure (Cheng and Furnham, 2003). The reliability value obtained in this study ($\alpha=.76$) confirmed the initial reliability of the measure. The results of the factor analysis showed one general factor (eigenvalue=8.7). This factor explained 32.51 percent of the variance. The factor loadings obtained were from .40 to .72 for items.

Results

Correlations, means and standard deviations for measured research variables are presented in Table 1.

Table 1
Means, Standard Deviations, and Correlations among the
Research Variables

	mean	SD	1	2	3	4	5	6	7	8
Happiness	77.82	11.5	1							
Extravert	32.69	6.8	.33	1						
Neuroticism	27.06	6.4	-.39	.24	1					
Openness	35.26	5.6	.20	.44	-.09	1				
Conscientiousness	22.01	3.7	.09	-.1	-.33	-.04	1			
Agreeableness	36.8	5.2	.29	.56	-.33	.26	.25	1		
Intrinsic	29.2	5.5	.32	.04	-.45	.12	.24	.11	1	
Extrinsic	14.9	4.01	-.08	-.12	.17	-.01	-.19	-.17	-.28	1

Results of Pearson correlation coefficients among the research variables, as presented in Table 1, revealed that extraversion was positively related to happiness ($r = .33, p < .001$) and neuroticism was negatively related to it ($r = -.39, p < .001$). Neuroticism, as shown in Table 1, was negatively related to intrinsic religious orientation ($r = -.45, p < .001$) and conscientiousness and agreeableness were negatively related to extrinsic religious orientation ($r = -.19$ and $r = -.17, p < .01$). Finally, results showed that intrinsic religious orientation was positively related to happiness ($r = .32, p < .001$).

Predicting Happiness from Personality Traits and Religious Orientation

A simultaneous hierarchical regression, based on Baron and Kenny's steps (1986), was applied to test the research hypotheses. Their steps required the followings:

- 1-Enter regression of happiness on Personality dimensions
- 2-Enter regression of religious orientation on Personality dimensions
- 3-Enter regression of happiness on religious orientation and Personality dimensions
- 4-compare steps 1 and 3

Step1

Relations between the Big Five Personality Traits and Happiness

The results of multiple regressions (enter) of happiness on personality variables are presented in Table 2.

Table 2
Multiple Regression of Personality on Happiness

Predictors	<i>R</i>	<i>R</i> ²	<i>F</i>	<i>B</i>	<i>B</i>	<i>T</i>	<i>sig</i>
Neuroticism	.47	.22	16.48	-.79	-.33	-5.7	.001
Extraversion				.62	.18	2.6	.001
Openness				.32	.08	1.24	N.S
Conscientiousness				.28	.043	1.1	N.S
Agreeableness				.29	.055	.87	N.S

As the results of Table 2 show the initial regression was significant ($F=16.48$; $P<.001$; $R^2=.22$). The extraversion ($\beta=.18$, $t=2.6$, $p<.001$), and neuroticism ($\beta=. -33$, $t= -5.7$, $p<.001$) significantly predicted happiness

Step 2

A). Relations between the Big Five Personality Traits and Intrinsic Religious Orientation

The results of multiple regressions (enter) of personality traits on intrinsic religious orientation are presented in Table 3.

Table 3
Multiple Regression of Personality on Intrinsic Religious Orientation

Predictors	<i>R</i>	<i>R</i> ²	<i>F</i>	<i>B</i>	<i>B</i>	<i>T</i>	<i>sig</i>
Neuroticism	.49	.24	18.3	-.11	-.44	-7.79	.001
Extraversion				.52	.088	1.32	N.S
Openness				.71	.14	2.42	.001
Conscientiousness				.67	.11	2.01	.001
agreeableness				.34	-.04	.68	N.S

As the results of Table 3 shows the initial multiple regression was significant (($F=18.3$; $P<.001$; $R^2= .24$) Results of enter regression procedure indicated that neuroticism ($\beta=-.44$, $t= -7.79$, $p<.001$), openness ($\beta=.14$, $t= 2.42$, $p<.001$.) and conscientiousness ($\beta=.11$, $t= 2.01$, $p<.001$) significantly predicted the intrinsic religious orientation as a dependent variable.

B). Relations between the Big Five Personality Traits and Extrinsic Religious Orientation

The results of the multiple regressions of the personality traits on the extrinsic religious orientation are presented in Table 4.

Table 4
Multiple Regression of Personality on Extrinsic Religious Orientation

Predictors	R	R²	F	B	B	T	sig
Neuroticism				.99	.09	1.34	.083
Extraversion	.36	.13	8.86	.42	.05	.79	N.S
Openness				.71	.08	.87	N.S
Conscientiousness				-.98	-.18	-3.7	.001
agreeableness				.35	.04	.68	N.S

As the results of Table 4 shows the initial multiple regression was significant (F=8.86; P<.001; R²=13). Results showed that conscientiousness (β =-.18, t= -3.7, p<.001) was a negative significant predictor of the extrinsic religious orientation.

Predicting Happiness from Personality Traits and religious Orientation

Step3

Applying the third step of the multiple regression, all variables were entered together to predict happiness. The purpose of this step was to identify the role of the religious orientation as a mediator variable.

As Table 5 shows the results of regression was significant ((F=14.1; P<.001; R²=.27). The results showed that extraversion (β =.21, t=2.97, p<.001), neuroticism (β =-.24, t=-3.7, p<.001) and intrinsic religious orientation (β =.212, t=3.6, p<.001) significantly predicted happiness.

Table 5
Multiple Regressions of Personality and Religious
Orientation on Happiness

Predictors	R	R²	F	B	B	T	sig
Neuroticism	.52	.27	14.1	1.21	-.24	-3.7	.001
Extraversion				1.13	.21	2.97	.001
Openness				.69	.07	.68	N.S
Conscientiousness				.63	.088	1.1	N.S
Agreeableness				.55	.06	.71	N.S
Intrinsicreligiouso rientation				.99	.21	3.6	.001
extrinsic religious orientation				-.63	-.05	.81	N.S

Step 4

Comparing the results of steps 1 and 3 indicates that religious orientation plays a significant mediator role between personality traits and happiness. The total model, after eliminating no significant relationships, is shown in Figure 1.

To evaluate the model, multiple indexes of fitness such as;GFI=.96, AGFI=.92, RFI=.95 and RMSEA=.05were used which showed desirable fitness of the model.

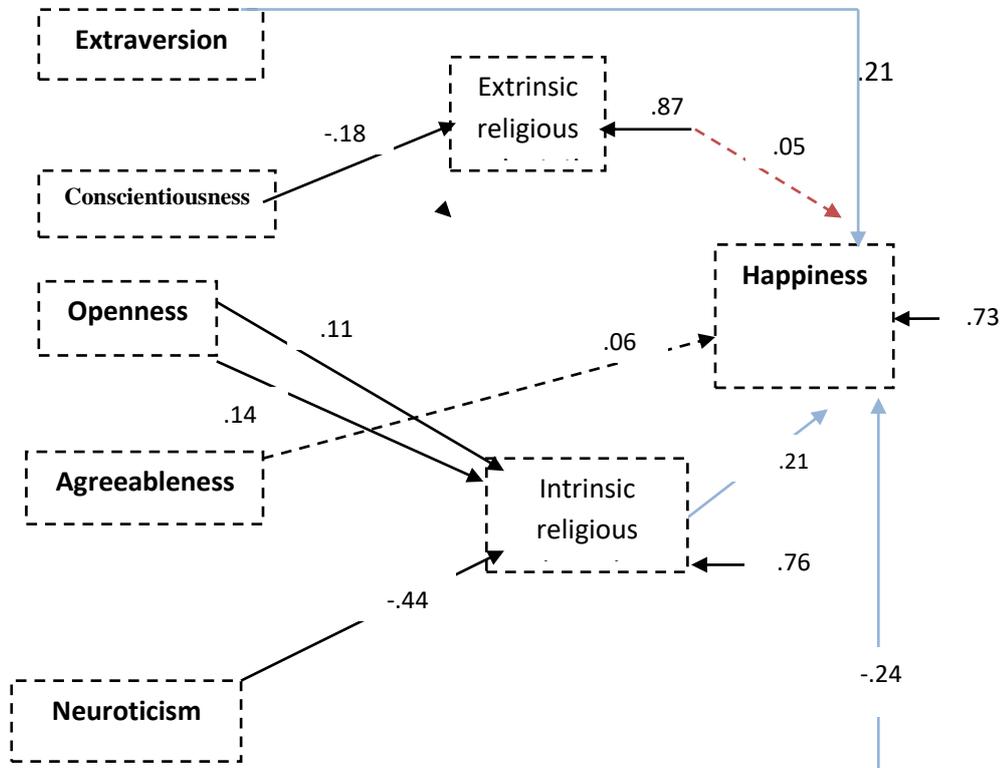

Figure 1 ◀
The Total Model

Discussion

The main goal of this study was to investigate the relationship between the five-factor model of personality and happiness with the mediator role of religious orientation. Results of this study, initially, supported the first hypothesis. Consistent with the previous studies in the field, neuroticism was negatively related to happiness and extraversion was positively related to happiness. Similar results were obtained by (Eysenck, 1990; Argile, 1990; Furnham and Cheng, 2000; Cheng, and Furnham, 2003; Francies, 2000; Mazidi & Ostovar, 2006;

khanzade, Moltafet & Sadati, 2007). The above researchers have shown that extraversion and neuroticism had direct effects on happiness. Results of this study provided support for the first hypothesis.

In order to examine the relationship between personality traits and religious orientations, two separate regressions were performed; one for intrinsic and another for extrinsic religious orientations. Results of the regression procedure revealed that conscientiousness, and openness were positively, and neuroticism was negatively related to intrinsic religious orientation. However, conscientiousness predicted extrinsic religious orientation negatively. Previous researchers such as Francies (1992), Lewis & Maltby (1995), Maltby (1999) and Gorm (2004) supported our results and showed that psychoticism and neuroticism were negatively related to intrinsic religious orientations. Therefore, the findings that conscientiousness and openness were positively related to intrinsic religious orientation are unique.

Since the main goal of this study was to explore the relationship between personality traits and happiness, with religious orientation as a mediator variable, we performed regression procedures to predict happiness using all research variables. The results of regression showed that religious orientation plays a mediation role between personality traits dimensions and happiness nicely. Previous researchers such as Francis (2000, 2002); maltby & Day (2003) and mazidi & Ostovar (2006) supported our results and showed that religious orientation was related to well-being and happiness.

Combination of the variables in this model is, by itself, the most significant characteristic of this research. Therefore, the current finding could be regarded as one of the most important contributions of this study. This model is a proper model to

explain the mechanism of the effects of personality traits on happiness. In sum, the present study adds to the growing body of literature surrounding personality and its outcomes. It demonstrates that the unique influence of the separate components of religious orientation on happiness and religious orientation depends on the personality. In order to increase the level of happiness in neurotic people it would seem useful to intervene by increasing intrinsic religious orientation. In other words, one way to help people to better "pursue happiness" may be to help them to better identify and pursue personal goals such as intrinsic religious orientation. The model applied in this study has an important implication for future research, especially research on religiosity. The finding that religion orientation plays a significant role on the relationship between personality traits (big five) and happiness, has more illuminated the nature of this relation. Also it seems that individual's happiness is, to some degree, affected by his/her religious orientation. Individuals with an intrinsic religious orientation were happier than those with an extrinsic orientation. Therefore, it is recommended that the ground for experiencing more intrinsic religious orientation should be provided for the people. Results of this study are limited to the population from which our research sample was selected. Therefore, generalizations of our findings to other groups, in Iran, or individuals in other countries are not recommended. Further, studies should check this model to verify whether it is applicable to cultural settings other than the Islamic tradition or not.
