The purpose of this study was designing and testing a model of some antecedents of subjective career success. The participants of this study consisted of 230 employees of Khuzestan Water and Power Organization, who were selected by stratified random sampling method. The instruments used in the study were Work Climate Questionnaire, Perceived Competence Scale, Basic Need Satisfaction at Work Scale, Work Extrinsic and Intrinsic Motivation Scale, Career Satisfaction Scale, Perceived P-V Fit Scale & Career commitment Scale. Structural equation modeling (SEM) through AMOS-21 was used for data analysis. Bootstrapping procedure also used to determine the significance of the indirect effects. The results showed that the proposed model fitted the data properly. Findings showed that work autonomy support and work competency support had significant direct effects on need satisfaction, self-determined motivation, and career success (career commitment, career satisfaction, and perceived p-v fit). Results also supported the mediating role of need satisfaction and self-determined motivation in these relationships. Based on our findings, SDT is a useful framework for predicting subjective career success in the form of career satisfaction, career commitment, and perceived p-v fit.

Keywords: subjective career success, self-determined motivation, need satisfaction, work autonomy support, work competency support
Career is a pattern of work-related experiences that continues throughout one's life. Career is a collection of personal learning and experiences related to work along the way of life. Career success is a set of positive and psychological consequences that derive from individual work experience (Seibert, Kraimer & Crant, 2001). A successful career implies achievement of the specific desired of an individual in his or her career (Dolan, Bejarano & Tzafrir, 2011).

Individual can identify their career success by comparing what has already been achieved with desired goals. Career success is divided into objective career success and subjective career success. Objective career success is defined by reference to societal or cultural factors and includes lateral (increased job security, longer vacations) or hierarchical (promotion, different job title) factors (Karavardar, 2014; Rasdi, 2011). Subjective career success is defined as individuals perceptional evaluations of, and affective reactions to, their careers according to subjective criteria such as age, functional stage, career aspirations, and opinions of others, as well references to personal standards and perceived among individuals for life satisfaction in general, and the balance between career and family life (Kong, Cheung & Song, 2012; Colakoglu, 2011).

The objective career success is measured by the consequences given to a person from an outside person. There is no interpretation here, but only a comparison of the levels of external achievements. Subjective career success depends only on what remains in the individual's mind, even if those feelings and perceptions arise from external facts such as rights or promotions (Deris, Pepermans & Carlir, 2008).

Researchers report that an increasingly large percentage of employees define their career success in terms of subjective
Designing and Testing a Model of some Antecedents of Subjective …

indicators rather than objective ones (Littler, Wiesner & Dunford, 2003; Sturges, 2002). Chen (2011) mentioned that subjective career success consist of job and career satisfaction. Ng & Feldman (2014) concluded that job dissatisfaction, Low organizational commitment, Low occupational commitment, Low work centrality, Low job motivation, Low job involvement, and Low work engagement are associated with lower subjective career success.

Feelings of subjective career success are important to the well-being of individual, but they have serious for organizations as well. For example, employees with positive career beliefs are better able to maintain work-life balance (Sturges, 2002) and are more likely to remain with their employers and persist when confronted with vocational challenges (Armstrong-Stassen & Ursel, 2009; Donohue, 2007; Eddleston, 2009; Nauta, Van Vianen, Van Der Heijden, Van Dam & Willemsen, 2009).

Conversely, workers with negative career attitudes are more likely to withdraw from jobs and even change vocations (e.g., Simon, Muller & Hasselhorn, 2010). Therefore, recognizing the experiences that will create a positive attitude and career success will be important both for individuals and for the organizations that hires these people. Career success is a topic that affects not only individuals but also organizations, because individual employee success eventually brings organizational success (Judge, Higgins, Thoresen & Barrick, 1999). Much recent has focused on describing the antecedents of subjective career success, including personality traits (Judge et al., 1999; Ng et al., 2005). And employees' demographic characteristics (i.e., job tenure, education, and work experience; Ng et al., 2005).

Self-determination theory (SDT) proposes that certain job characteristic that satisfy employees’ fundamental psychological
needs will generate self-determined motivation for work. This contextual motivation for work, in turn, encourages people to persist with their work behavior (Vallerand, 1997). SDT has implications for subjective career success: When people experience strong work motivation, they should feel ownership over their careers, choose to remain on their career track, and feel that they are making successful career progress. This proposition aligns with recent developments in career theory that emphasize the importance of self-directed career orientations (Sullivan & Baruch, 2009).

In this study we focus on specific job characteristics that are drawn from SDT: Autonomy support and competence support. Autonomy support refers to work experiences that bolster employees’ feelings of choice and agency over their jobs. Competence support refers to job experiences that allow employees to feel capable when working (Deci & Rayan, 2012). These job characteristics will be positively associated with need satisfaction, self-determined motivation, and, ultimately, subjective career success (Judge, Cable, Boudreau & Bretz, 1995; Seibert, Crant & Kraimer, 1999; Seibert, Kraimer & Crant, 2001). Fu (2010) defined career satisfaction as the level of overall happiness experienced through one’s choice of career. Subjective career success is typically defined in terms of career satisfaction, which involves positive attitudes that a person holds about the progress and future trajectory of his or her career (Greenhaus, Parasuraman & Wormley, 1990). Other variable include career commitment, which involves an attachment to a vocation or profession and desire to continue practicing it (Blau, 1985), and perceived person-vocation (P-V) fit, which involves beliefs that one’s interests and abilities are match to the requirements of a vocation (Vogel & Feldman, 2009).
Autonomy support and competence support will have an important impact on need satisfaction. According to cognitive evaluation theory (CET), a person who experiences the feeling of ability and competence in a job will be satisfied with her or his job (Deci & Rayan, 2012). Additionally, need satisfaction can be an intermediary between job characteristics and self-determined motives. When people fulfill their basic needs, they experience self-identified motivation for work behaviors (Deci & Rayan, 2012). The self-determined motives subsequently have impact on the career dimensions. These relationships should be positive, intuitively pleased people derive from independent and committed behaviors that are likely to fulfill their needs and report on proportionality and commitment when they are motivated by self-regulation (Deci & Rayan, 2000; Meyer & Maltin, 2010; Greguras & Diefendorff, 2009; Meyer & Gagne, 2008).

Autonomy support and competence support have direct effects on the psychological perception of satisfied needs (Deci & Rayan, 2012), need satisfaction, in turn subsequently promotes self-determined motivation (Vallerand, 1997). Thus, job contexts that enhance feelings of autonomy and competence should be associated with the perception of need satisfaction, and need satisfaction should mediate the relationships between the job context and self-determined motivation. Critically, need satisfaction and self-determined motivation will be stymied if one support or the other is absent. For example, people may feel confident, but when given an external reward or punishment that reduces autonomy support, self-determined motivation will be undermined (Deci & Rayan, 2000).
Overview of the SDT

SDT argues that an autonomous act is defined as regulation by the self, the self being a central process that regulates behavior and experience. It is an organismic theory that accepts that human have a natural propensity to grow and assimilate aspects of their environment. Behavior is essentially the product of the interaction between the organism and the environment. SDT is a motivational theory that focuses on the regulatory processes by which individuals pursue goals in order to satisfy their innate psychological needs (Deci & Rayan, 2000, 2012; Ryan & Deci, 2000). SDT is considered a meta-theory of motivation because its propositions were developed over the last 40 years through several narrower that reside within SDT (Deci & Rayan, 2012). At its most basic level, SDT proposes that people have fundamental needs for autonomy, competence and relatedness and that they experience self-determined motivation for activities that satisfy those needs. In this study, we focus on one sub-theory within SDT, cognitive evaluation theory (CET), which is primarily concerned with needs for autonomy and competence. We chose CET because needs for autonomy and competence can be satisfied in any job. In contrast, the third need introduce in later sub-theories, relatedness, may not be as readily addressed in jobs that are performed individually.

CET identifies the situational conditions that satisfy people’s fundamental needs for autonomy and competence (Ryan & Deci, 2000). Autonomy describes the need to have personal agency and to act in a way that is authentic and agrees with one’s sense of self. Competence refers to the need to feel capable of being able to achieve specific outcomes and gain mastery over a performance domain. CET posits that people will experience self-
determined motivation in situation that promotes the satisfaction of autonomy and competence.

Modern job design is broadly concerned with way that jobs are structured and experienced by employees (Nahrgang, Morgeson & Hofmann, 2011), moving beyond a specific focus on tasks and responsibilities that characterized early job design scholarship (Grant et al., 2010; Hackman & Oldham, 1976). Contemporary approaches recognize that jobs can be designed in ways that promote a bevy of desirable outcomes for workers and organizations, including learning, well-being, and work-family balance (Parker, 2014). Motivation theories, including SDT, also play a prominent role in this literature. Job design research based on SDT tends to emphasize the benefits of providing employees with autonomous choice (e.g., Baard, Deci & Rayan, 2004; Deci, Rayan, Gagne, Leone, Usunov & Kornazheva, 2001; Fernet, Austin & Vallerand, 2012; Sheldon, Turban, Brown, Barrick & Judge, 2003) and the effects of self-determined motivation on job outcomes such as job satisfaction, burnout, organizational identification, and turnover intention (Gillet, Gagne, Sauvagere & Fouquereau, 2013; Lam & Gurland, 2008; Vansteenkiste & Ryan, 2013). In aggregate, structuring jobs to fulfill fundamental needs leads to many positive job outcomes for both employees and organizations.

Although career theory has developed separately from job design theory, contemporary career theory invokes similar ideas from SDT. In response to environmental challenges (e.g., globalization, advances in technology) and personal factors (e.g., an emphasis on work-life balance, dual career families), many employees are no longer following the traditional, linear career path. Rather, employees are striving to pursue career focuses on several career orientations that people adopt to be successful in
response to these changes (Sullivan & Baruch, 2009). Protean career orientation, for example, refers to career development that is self-directed and driven by personal values. Protean careerists do not define success in the traditional way (i.e., status) but instead derive it from personal goal achievement, pride, and psychological success (McArdle, Waters, Briscoe & Hall, 2007; Hall, 1996). A related stream of career theory focuses on boundaryless career orientation, which emphasizes both psychological and physical mobility that defies the traditional, linear career trajectory. The behaviors of boundaryless careerists are self-determined (McArdle et al., 2007).

To summarize, we chose to explain the effects of job design on subjective career success with SDT in this study because concepts from SDT are deeply entrenched in both the job design and career theory literatures. Research situated in job design theory demonstrates that need-fulfilling job characteristics yield powerful, self-determined motivation. Similarly, research situated in career theory shows that people who adopt orientations that capitalize on self-determined motivation to guide their own career development, tend to experience better subjective outcomes.

**The Present Study**

We first hypothesized that autonomy-supportive and competence-supportive job characteristics positively affect need satisfaction at work. According to CET, jobs that promote feelings of agency and capability will satisfy employees’ fundamental needs for autonomy and competence (Deci & Rayan, 2012). CET further posits that need satisfaction will mediate the relationships between job characteristics and self-determined motivation for work. Lastly, SDT posits that the effects of need
satisfaction on career attitudes should occur via self-determined motivation. As noted previously, people experience self-determined motivation for work behaviors when work fulfills their fundamental needs (Deci & Rayan, 2012). Self-determined motivation should subsequently have positive effects on career attitudes (i.e., career satisfaction, career commitment, and P-V fit). These relationships should be positive because people derive satisfaction from autonomously performed behaviors (Deci & Rayan, 2000), are likely to become committed to entities that fulfill their needs (Meyer & Maltin, 2010), and report feelings of fit and engagement when autonomously motivated (Greguras & Diefendorff, 2009; Meyer & Gagne, 2008).

The purpose of the current study is to expand on prior research by examining these relationships. The objective of this study is to demonstrate how job design (i.e., work autonomy and work competence support) is predictive of subjective career success (i.e., career satisfaction, career commitment, and perceived P-V fit) via need satisfaction and self-determined motivation (see Figure 1).

**Figure 1. The Proposed Model of the Current Research**
Method

Participants and Procedure

The statistical population of this research included all employees of Khuzestan water and power organization. For using structural equation modeling (SEM), Kline (2011) stated that the sample size ratio for each estimated parameter is at least 5 and at the most 20. According to the number of parameters in the proposed model, the participants consisted of 260 employees of the statistical population who were selected by stratified random sampling method. Anonymous questionnaires were distributed and altogether, 230 questionnaires were returned, yielding a response rate of 88%. Of the employees in the final sample, 77.3% were men. The average age was 41.09 years (SD=7.87), and the average tenure was 15.5 years (SD=7.33).

Instrument

Work Climate Questionnaire

We measured autonomy-supportive work conditions with the 6-item Work Climate Questionnaire (WCQ; Baard et al., 2004; \( \alpha = .94 \)). The WCQ evaluates perceptions of the extent to which managers in the workplace promote autonomy; a sample item read, "I feel that my manager provides me choices and options." Responses were made on a 7-point Likert-type scale from 1 (strongly disagree) to 7 (strongly agree). In the present study Cronbach’s alpha was .90. In order to determine the validity of this questionnaire, a confirmatory factor analysis (CFA) was conducted. The results showed that all items (except items 1 & 3, which had factor loadings less than .3) had good factor loadings; i.e., all items loaded significantly on related factors. This provided evidence for the construct validity of this questionnaire.
Perceived Competence Scale

Competence support was measured with the 4-item (α=.92) Perceived Competence Scale (PCS; Williams & Deci, 1996). Because the PCS items are intended to be domain specific, we followed past practice to modify the target of the questions to pertain to work (cf. Williams, Freedman, & Deci, 1998, who modified the questions to concern perceived competence at managing diabetes). A sample item reads, "I am capable of meeting my bosses’ expectations of me at work"; responses were on a 7-point scale where 1 = not at all true and 7 = very true. Different forms of the PCS have been shown to be predictive of learning outcomes (Williams & Deci, 1996) and behavioral outcomes (Williams et al., 1998). In the present study Cronbach’s alpha was .83. In order to determine the validity of this scale, a confirmatory factor analysis (CFA) was conducted. The results showed that all items had good factor loadings; i.e., all items loaded significantly on related factors. This provided evidence for the construct validity of this scale.

Basic Need Satisfaction at Work Scale

We used the Basic Need Satisfaction at Work Scale (Deci et al., 2001) to measure satisfaction of fundamental needs. We used only the 13 items from this scale pertaining to satisfied autonomy and competence needs (α=.88). Sample items read, "I feel like I can pretty much be myself at work "(autonomy fulfillment). Responses were made on a 7-point scale where 1 = not at all true and 7 = very true. In the present study, Cronbach’s alpha was .73. In order to determine the validity of this scale, a confirmatory factor analysis (CFA) was conducted. The results showed that all items (except items 4 & 7, which had factor loadings less than .3) had good factor loadings; i.e., all items loaded significantly on
related factors. This provided evidence for the construct validity of this scale.

**Work Extrinsic and Intrinsic Motivation Scale**

Work motivation described SDT was measured with the 18-item Work Extrinsic and Intrinsic Motivation Scale (WEIMS; Tremblay, Blanchard, Taylor, Pelletier & Villeneuve, 2009). The WEIMS was developed by translating the short version of the Blais Work Motivation Inventory (Blais, Lachance, Vallerand, Briere & Riddle, 1993), a validated French language instrument, to English and making slight adjustments to some items for semantic clarity. The WEIMS is a validated measure of all six work motivations described by organismic integration theory: intrinsic ($\alpha=.92$), identified ($\alpha=.84$), integrated ($\alpha=.88$), introjected ($\alpha=.84$), external ($\alpha=.70$), and amotivated ($\alpha=.79$). Each motivation type is measured with 3 items presented in a randomized order. Participants indicated the extent to which each item corresponds with the reasons why they work; sample items, "For the income it provides me" (external), "For the satisfaction I experience from taking on interesting challenges" (intrinsic), and "Because I want to succeed at this job, if not I would be very ashamed of myself " (introjected). Responses were made on a 7-point scale where 1=does not correspond at all and 7=corresponds exactly, such that higher scores indicate greater endorsement of a particular type of motivation.

Following established practice in the SDT literature (e.g., Rayan & Connell, 1989), Tremblay et al., (2009) converted the motivation scale scores into an overall self-determination index (SDI), where $\text{SDI} = (3 \times \text{intrinsic}) + (2 \times \text{integrated}) + (1 \times \text{identified}) + (-1 \times \text{introjected}) + (-2 \times \text{external}) + (-3 \times \text{amotivation})$. We use the SDI in the analyses that follow to give
Designing and Testing a Model of some Antecedents of Subjective …

an overall evaluation of self-determination; positive scores indicate relatively self-determined motivation, and negative scores indicate relatively non-self-determined motivation. Possible scores range from -36 to +36. In the present study, Cronbach’s alpha was .87. In order to determine the validity of this scale, a confirmatory factor analysis (CFA) was conducted. The results showed that all items (except items 6, 8 & 15 which had factor loadings less than .3) had good factor loadings; i.e., all items loaded significantly on related factors. This provided evidence for the construct validity of this scale.

**Career Satisfaction Scale**

Career satisfaction was measured with Greenhaus et al. (1990) 5-item measure (α=.96). Sample items read, "I am satisfied with the success I have achieved in my career" and "I am satisfied with the progress I have achieved in my career goals." Responses were made on a 7-point scale where 1 = strongly disagree and 7= strongly agree. This measure is correlated with job attitudes as job fit perceptions and job turnover intentions (Dahling & Thompson, 2013). In the present study, Cronbach’s alpha was .87. In order to determine the validity of this scale, a confirmatory factor analysis (CFA) was conducted. The results showed that all items (except item 1 which had factor loadings less than .3) had good factor loadings; i.e., all items loaded significantly on related factors. This provided evidence for the construct validity of this scale.

**Perceived P-V Fit Scale**

Perceived P-V fit was measured using the 3-item measure (α=.81) developed by Vogel and Feldman (2009). A sample items reads, "There is a good fit between my personal interests and the kind of work I perform in my occupation." Responses were made on
a 7-point scale where 1 = strongly disagree and 7 = strongly agree. In the present study Cronbach’s alpha was .70.

**Career commitment Scale**

Career commitment was measured with Blau’s (1985) 7-item measured (α=.93). A sample item reads, "If I could go into a different profession which paid the same, I would probably take it" (reverse-scored). Responses were on a 7-point scale where 1 = strongly disagree and 7 = strongly agree. In the present study Cronbach’s alpha was .76. In order to determine the validity of this scale, a confirmatory factor analysis (CFA) was conducted. The results showed that all items (except item 1 which had factor loadings less than .3) had good factor loadings; i.e., all items loaded significantly on related factors. This provided evidence for the construct validity of this scale.

**Results**

**Descriptive Statistics**

To start with all proposed relationships were tested simultaneously; first a correlation analysis was conducted (Pearson correlation) among all the variables included in this study. The correlations among variables, means, and standard deviations are reported in Table 1.

Structural equation modeling results suggested that the hypothesized model fit the data adequately, $\chi^2=4.71$; df=3; $p>.05$; $\chi^2$/df=1.57; GFI=.99; AGFI=.94; CFI=.99; IFI=.99; TLI=.97; NFI=.99; RMSEA=.05.

The standardized regression weights for the paths are shown in Figure 2.
As shown in Figure 2, all paths in this model were statistically significant (p<.01). Because of the proposed mediation effects, bootstrapping procedure was used to determine the significance of these effects. Bootstrapping procedure (using 1000 re-sampling) was used to determine the 95% bias-corrected confidence intervals around these effects. A confidence interval that did not span zero indicated a statistically significant effect. Table 2 indicates the results for bootstrapping analysis.

As shown in Table 2 the eight confidence intervals, did not span zero that indicates statistically significant mediation effects.

Discussion
The aim of the present study was designing and testing a model of some antecedents of subjective career success. The relationships in this model, which had received support from previous studies, were examined with data from employees in an industrial organization in Ahvaz, Iran. Promoting subjective career success has important benefits for employees, organizations, and professions, but researchers have neglected the ways that job design can translate into broader career outcomes (Hall & Las Heras, 2010). The present study tested how SDT, and especially the sub-theory of CET, explains this process. Our results supported all paths in the proposed model. Findings showed that autonomy support and competence support had direct effects on need satisfaction, self-determined work
motivation, and career success (career commitment, career satisfaction, and perceived p-v fit). Also, the effects of autonomy support and competence support on self-determined work motivation were fully mediated by need satisfaction. Self-determined work motivation also mediating the relationship between autonomy support and competence support with career success (career commitment, career satisfaction, and perceived p-v fit).

These finding help to confirm that the literature regarding job design and career development are closely related. Pervious research has focused predominately on personality traits and relationship-based variables, such as supervisor support, as antecedents of subjective career success (Ng et al., 2005). Our study expands the network around career success to include job characteristics which organizations can control them.

Our results also contribute to the literature regarding the importance of SDT in the workplace (Gagne & Deci, 2005; Sheldon et al., 2003). Although some authors have criticized the relevance of SDT (Fay & Frese, 2000; Latham, 2013), our results demonstrate that autonomy and competence supports contribute to self-determined motivation and valuable career-related outcomes. More generally, our findings also illustrate the importance of considering how broader theories of human motivation can shape specific vocational processes and outcomes of interest to career counselors as Dahling & Librizzi (2015) observed.

The proposed model also showed a strong test of the propositions of CET and reinforces the validity of this theory. As Latham (2013) observed, many studies have not explicitly measured the mediating states theorized to operate in SDT, especially need satisfaction.
Promoting subjective career success has important benefits for employees, organizations, and professions, but researchers have neglected the ways that job design can translate into broader career outcomes (Hall & Las Heras, 2010). The present study tested how SDT, and especially the CET, explains this process. Our results supported that autonomy support and competence support had direct effects on the satisfaction of needs.

The results also suggest that career counselors should carefully assess and consider the work conditions reported by clients. Many occupations, such as nursing, struggle with retaining people in the profession due to occupational stressors (Simon et al., 2010). However, according to SDT and the results of our study, any type of work may be structured in ways that fulfill innate psychological needs and promote high levels of subjective career success. For example, giving employees some personal agency in their everyday tasks may help to promote a feeling of work autonomy (e.g., Fernet et al., 2012). Providing competence-enhancing feedback, as well as assigning challenging tasks, may similarly allow employees to feel confident that they can successfully complete their work (Deci et al., 2001). These efforts may yield self-determined job motivation and better employee attitude.

Limitations and Future Research

It is important to highlight some limitations of the present study which can guide future research. First, SDT includes many other sub-theories that we did not examine in this study. We excluded one sub-theory, causality orientation theory (e.g., Baard et al., 2004; Lam & Gurland, 2008), focuses on individual differences in terms of how people generally construe their motivations as autonomous, controlled, or impersonal. Future
research could extend our model by examining causality orientation as additional predictors or moderators of need satisfaction and motivation. Second, given the cross-sectional design of this study, causal relationships among the variables cannot be established. Longitudinal studies should be employed to test the hypotheses. Longitudinal research clarifies cause and effect relationships Third, the use of self-report measures may have inherent limitations (e.g., inability to recall, social desirability). A combination of self-report questionnaires and objective assessments would be ideal. Finally, because the participants were employees of Khuzestan Water and Power Organization, care should be taken in generalizing and extending the findings to other organizations’ employees.

Practical Implications

The inclusion of the proposed model in this research is a main contribution of this research. This provides a more accurate picture of the relationships in a specific setting and a specific culture. Even if clients do not report work conditions that satisfy innate needs, career counselors can work with clients to encourage independent job crafting that proactively fulfills their own needs (Berg, Wrezensniewski, & Dutton, 2010). Job crafting refers to self-initiated, rather than organization-initiated, actions to improve and enrich jobs to attain personal, work-related goals (Wrzesniewski & Dutton, 2001). Research on the measurement of job crafting indicates that crafting involves behaviors such as increasing social job resources and increasing challenging job demands (Tims, Bakker, & Derks, 2012). These behaviors should be particularly important for improving self-determined motivation and career attitudes because these dimensions contribute to fulfilling innate needs described by SDT. For
example, taking on and accomplishing challenging job demands should result in greater feelings of competence and autonomy satisfaction among workers.

Career counselors can also facilitate workers need fulfillment and self-determined motivation by encouraging clients to pursue flexible work programs, which provide employees with a high degree of autonomy over how, where, and when they perform their jobs (Kauffeld, Jonas & Frey, 2004). Sate for high work demands by giving workers enhanced autonomy, which resulted in greater employee learning and development. Flexible work programs should be particularly valuable to help employees fulfill needs for autonomy.

Conclusion
In sum, we linked the literatures on job design theory and career theory to demonstrate that SDT is a useful framework for predicting subjective career success in the form of career satisfaction, career commitment, and perceived P-V fit. Our model was fully supportive of all tested propositions and demonstrates that SDT has previously unexplored value for predicting career outcomes. Our findings have considerable practical importance as well; our results suggest that designing jobs in ways that satisfy innate psychological needs will boost work motivation and encourage workers to "stay the course" in their current careers.
